Linear regression models are often fitted using the least squares approach, but they may also be fitted in other ways, such as by minimizing the "lack of fit" in some other norm (as with least absolute deviations regression), or by minimizing a penalized version of the least squares cost function as in ridge regression (L 2-norm penalty) and lasso (L 1-norm penalty). Conversely, the least ...

But one of wonderful things about `glm()` is that it is so flexible. It can run so much more than logistic regression models. The flexibility, of course, also means that you have to tell it exactly which model you want to run, and how. In fact, we can use generalized linear models to model count data as well. In such data the errors may well be distributed non-normally and the variance usually ...

*Applying These Concepts to Overfitting Regression Models.*  
Overfitting a regression model is similar to the example above. The problems occur when you try to estimate too many parameters from the sample. Each term in the model forces the regression analysis to estimate a parameter using a fixed sample size. Therefore, the size of your sample restricts the number of terms that you can safely add ...

*R-squared is a goodness-of-fit measure for linear regression models. This statistic indicates the percentage of the variance in the dependent variable that the independent variables explain collectively. R-squared measures the strength of the relationship between your model and the dependent variable on a convenient 0 - 100% scale.*

*The basis of a multiple linear regression is to assess whether one continuous dependent variable can be predicted from a set of independent (or predictor) variables. Or in other words, how much variance in a continuous dependent variable is explained by a set of predictors. Certain regression selection approaches are helpful in testing predictors, thereby increasing the efficiency of analysis.*

*Logistic regression models a relationship between predictor variables and a categorical response variable. For example, we could use logistic regression to model the relationship between various measurements of a manufactured specimen (such as dimensions and chemical composition) to predict if a crack greater than 10 mils will occur (a binary variable: either yes*

or no). Logistic regression ...
